

Effects of siblings and pets on the developmental trajectory of human infant gut microbiomes, after antibiotic exposure

Marie Helene Munck Jørgensen, Malthe Sebastian Puro, Haopeng Wan

Background

The environment shapes our microbiota

The evolutionary link - the old friend hypothesis

Antibiotics influence how the microbiota is shaped - perturbs the natural equilibria

Critical window of opportunity

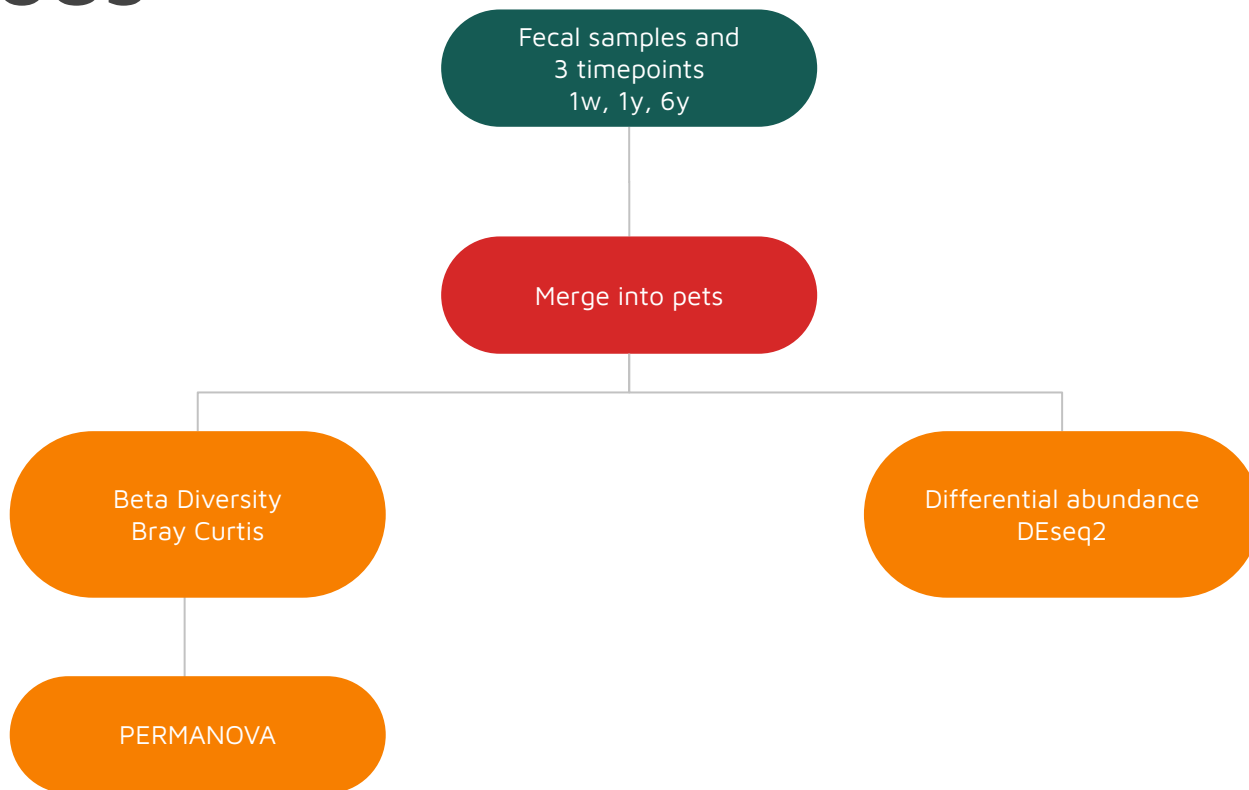

Pets and siblings introduce infants to microbes.

Hypothesis

Aims to investigate the effect that siblings or pets have on the developmental trajectory of the gut microbiota in a cohort of children, from the Copenhagen Prospective Studies on Asthma in Childhood₂₀₁₀ (COPSAC₂₀₁₀), who were exposed to antibiotics at birth.

Methods

Methods

Samples' group division

A Samples characteristics before merge(Feces)

		Cat_birth: 0	Cat_birth: 1	
		Time Period		
	Overall	1 week/No antibiotics at birth/ With antibiotics	1 year/No AB/With AB	6 year/No AB/With AB
	1363	683/330/153	560/383/177	320/221/99
Have any pets				
Yes	457	169/115/54	193/131/62	95/64/31
No	906	314/215/99	367/252/115	225/157/68
Have any sibling				
Yes	758	267/197/70	313/231/82	178/136/42
No	605	216/133/83	247/152/95	142/85/57

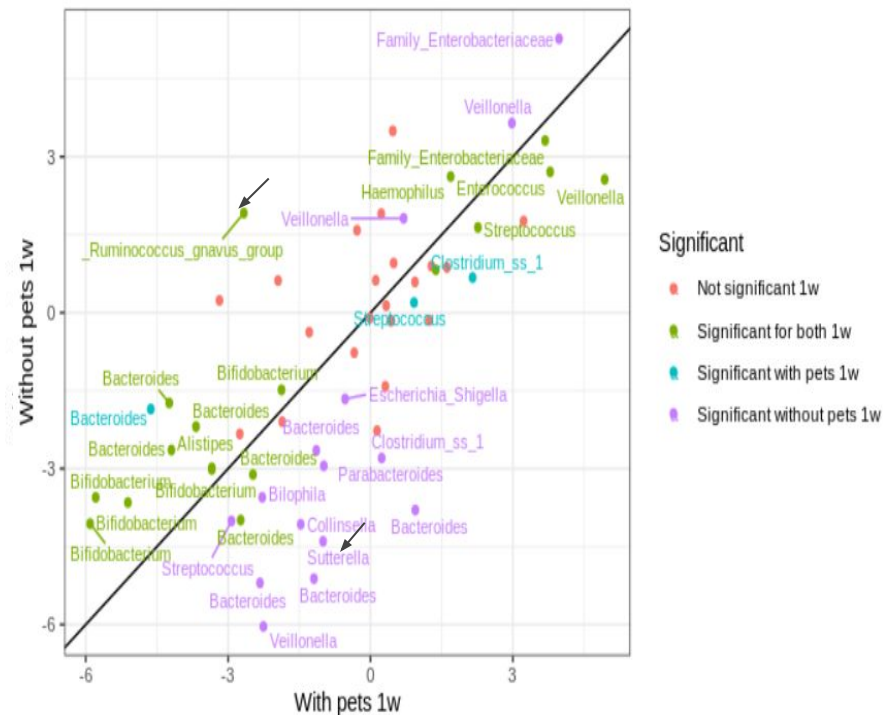

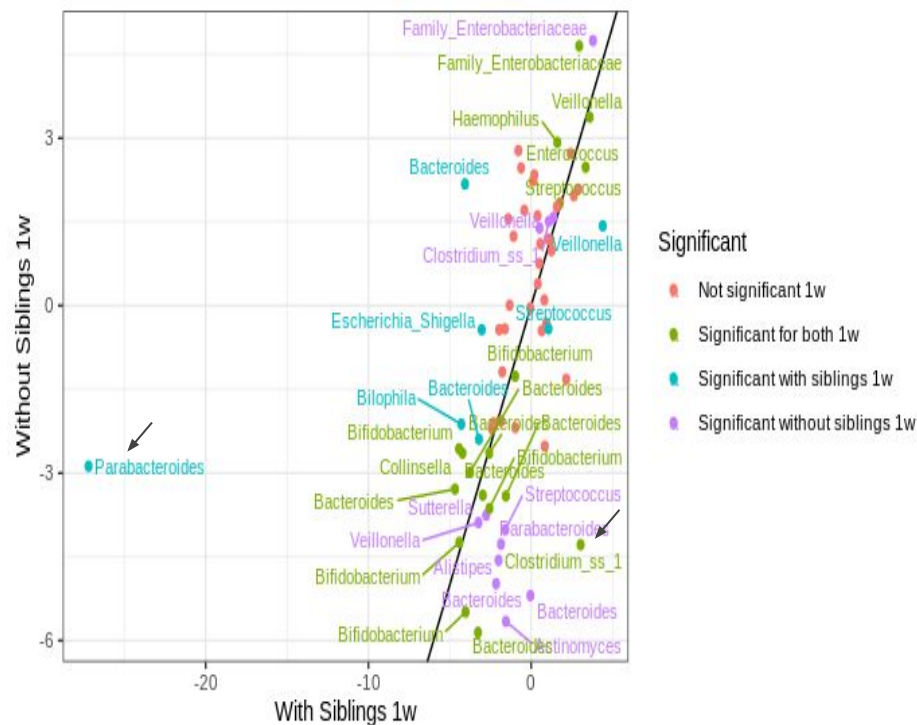

Results

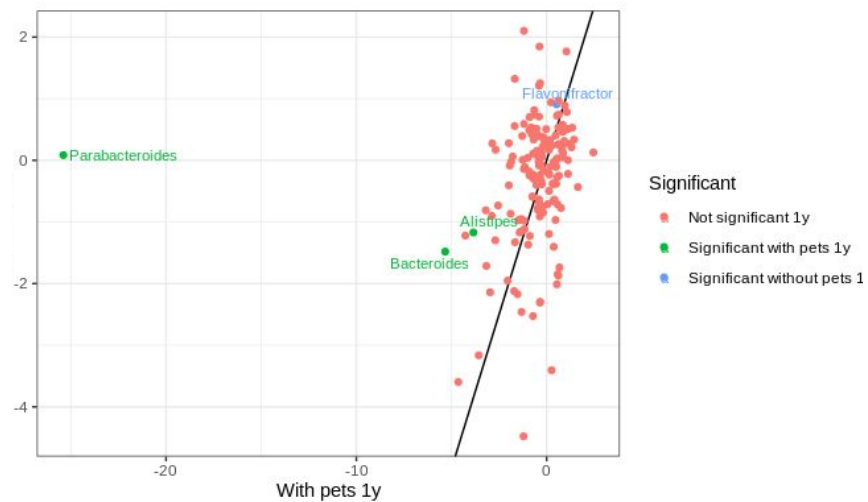

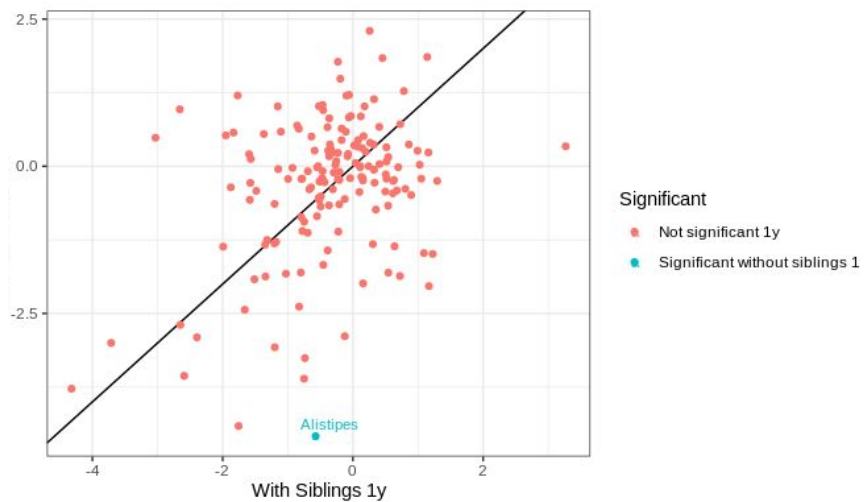

1. PERMANOVA of Bray-Curtis dissimilarity

Factor	Time point: Week 1		Year 1		Year 6	
	R ²	P-value	R ²	P-value	R ²	P-value
AB_birth	0.02921	0.001*	0.00397	0.007*	0.00387	0.164
Sibling	0.00635	0.001*	0.00832	0.001*	0.00490	0.025*
Pets	0.00350	0.047*	0.00133	0.801	0.00247	0.812
AB:Sibling	0.00141	0.832	0.00170	0.510	0.00335	0.332
AB:Pets	0.00155	0.715	0.00089	0.984	0.00207	0.958

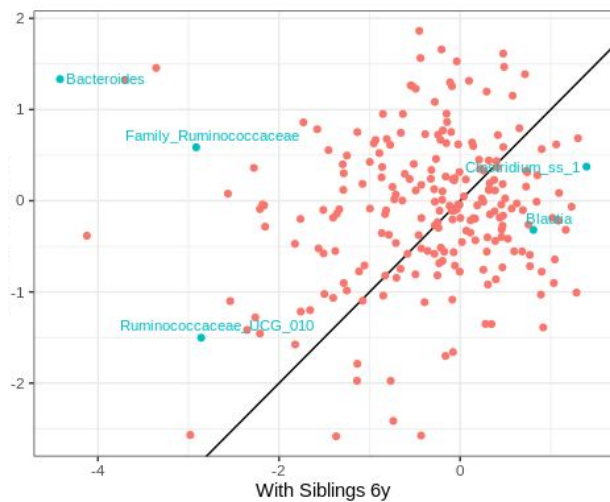

2. Differential abundance Week 1

Differential abundance year 1

Differential abundance year 6

Significant

- Not significant 6y
- Significant with siblings 6

Significant

- Not significant 6y
- Significant with pets 6y
- Significant without pets 6

Discussion

- **Beta diversity:** Factors are independent but have individual effect.
 - The effect of the factors decrease over time. → gut maturation (around two years)
 - Siblings vs pets: Harbour more relevant and closely related bacterial species to export
 - How the pets are kept?
- **Differential abundance:** Few species, with certain well described features, that were significantly different between the groups.
- Week one, large variation in species that are significantly associated with the presence or absence of either pets or siblings + compared groups have a lot of bacteria in common.
- Decrease over time.

Considerations

- Study design
- Subdividing pet/siblings
- Delivery mode
- Optimal if more timepoints

Conclusion

- **Beta diversity:** Antibiotic exposure at birth, showed significant impact on Bray-Curtis dissimilarity on week 1.
- Siblings sustained such effect significantly until year 6.
- Effects of antibiotics and pets fade.
- Need more information to test if the factors have an actual impact.
- **Differential abundance:** Several species or genus could be altered by the existence of siblings or pets; *Ruminococcus gnavus*, *Alistipes*, *Parabacteroides*. Those species are found to have relationships to certain disease or other physiological responses.
- Neither pets, siblings nor the interaction between those variables significantly changed the beta diversity of gut microbiome or last during infants' life (1 week, 1 year, 6 years), but this research revealed that certain species could be affected by those factors in terms of abundance.

Highlights

- ↓ ***Parabacteroides*** week with 1 sibling. Increased abundance linked to eczema
- ↑ ***Clostridium_ss_1*** + sibling, ↓ - sib.
 - Mediate the accumulation of Treg cells in mouse models, alleviating symptoms of allergies and Inflamed Bowel Disease (IBD)
 - Low levels of Clostridium correlated with the persistent atopic dermatitis
- ↓ ***Ruminococcus gnavus*** + pets, ↑ - pets: High abundance *R. gnavus* at an early age, correlated with the risk of developing respiratory allergies
- ↓ ***Sutterella*** - pets: The presence of sutterella can increase risk of developing environmental enteric dysfunction (EED).
- ↓ ***Alistipes*** + pets/sibling year 1. Significant for both sibling and pets: Lower abundance of Alistipes at 1 year samples were associated with development of asthma age 5, if the children were born to asthmatic mothers

Shaping of the gut microbiota

Which factors (environment, siblings, animals etc) have the largest influence on the shaping of the microbiome. / what bacteria do we lack and does it correlate with the results we see in the old friend hypothesis.

do we see an effect on the sibling ... ASK if we have data on the sibling.

Data from feces and from the lungs.

The variants or the evenness... Shannon for evenness.

How to separate the factors and we have to have a big cohort.

Check pcoa plot on environment and animals → how much does it vary from a “normal” microbiota.

environment include the animals and the other stuff to see how much of a difference it makes.

what bacteria are good for things. people in rural areas vs city has other bacteria??

Atopic bacteria due to lack of bacteria.. too clean!!! pathogens can stimulate immune system so you get less

Birth season

How does the season shape the microbiome?

(pollen and other allergens → people less allergic, when are they born.)

inside/winter and animals, does it do something.

file:///C:/Users/MAHEM/Downloads/children-07-00045-v2%20(3).pdf

Summer vitamin D. Does that have an effect on your microbiota.

siblings vs pets

Is there a difference between siblings animals after exposure to antibiotics. Also check born in different environments.

Do the long evolutionary relationship, and yet larger variance in microbiome in dogs and cats, make them more ideal for recovery of ab-altered microbiomes in human infants, relative to their siblings?

- What is a healthy microbiome for children?
- How do they recover after treatment of antibiotics. With and without pets/siblings.
-

Background

The environment shapes our microbiota

The evolutionary link - the old friend hypothesis

Antibiotics influence how the microbiota is shaped - perturbs the natural equilibria

Critical window of opportunity

Pets and siblings introduce infants to microbes.

Hypothesis

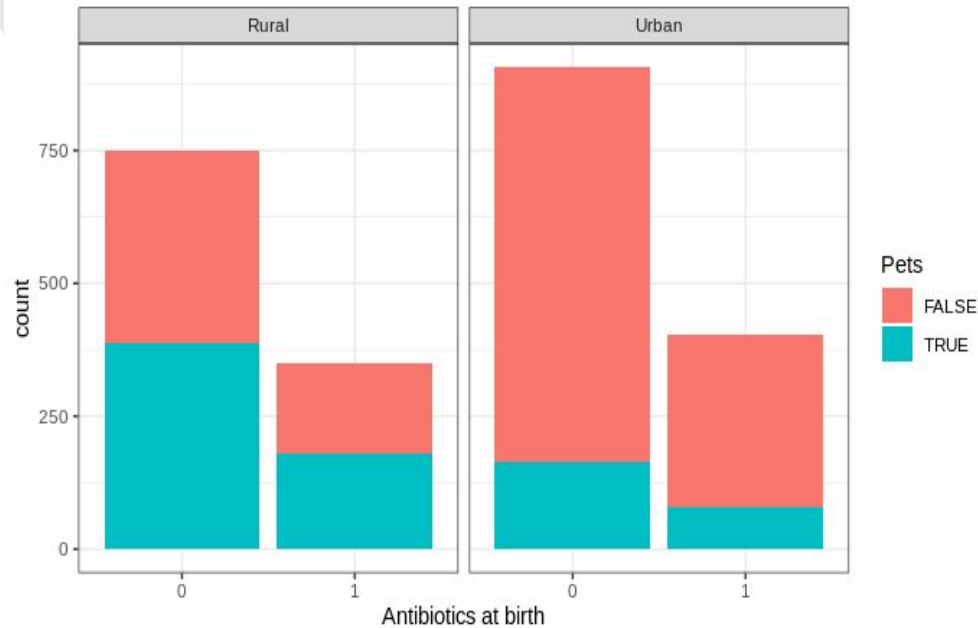

Are pets (dog and cats) associated with re-establishment of a “healthy” microbiome in children who have been exposed to antibiotics at birth? - if so, is the effect of having pets stronger compared to having siblings (hygiene regimen, evolutionary relationship and microbiome diversity)?

Process

How are we going to do it?

- Is there a significant taxonomic difference between rural and urban areas in our “0 pets / siblings” control group?
- If yes: do the analysis based on each environment (rural/urban)
- If no: concatenate data from each environment
- Analyse the temporal development of the microbiota (phylogeny) in the cohort who received antibiotics and had pets/no pets, and compare it to the control group.
- Figure out which parameter (sibling, dog or cat) have the greatest effect in the re-establishment of a normal microbiota.

#1 Do we see a significant phylogenetic difference in the two environments

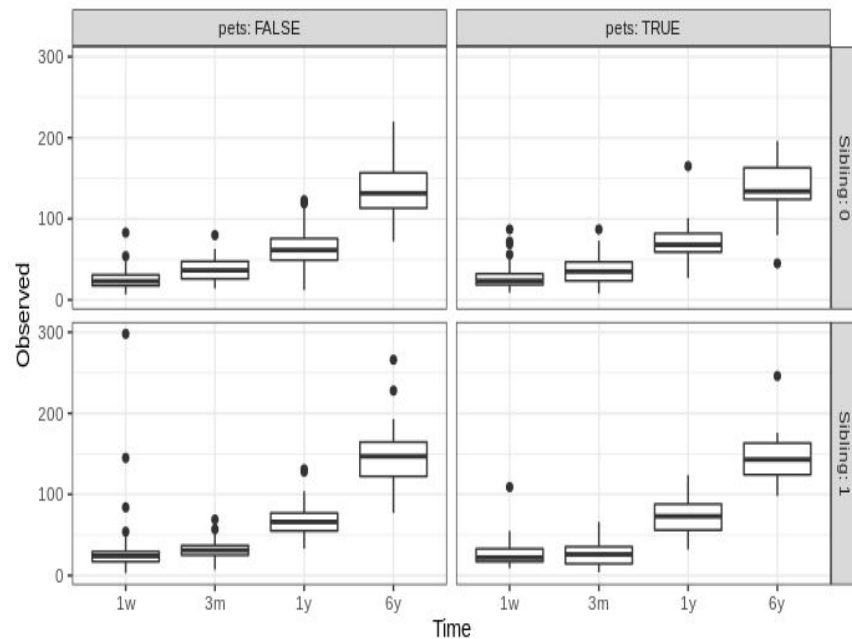

Merge data for cats and dogs

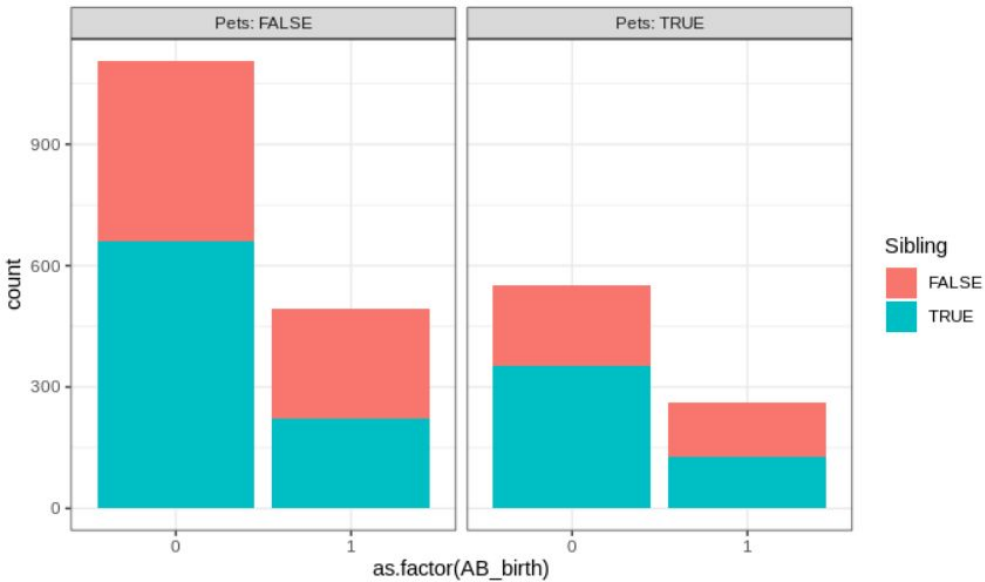

shannon alpha for antibiotic-treated only

observed alpha for antibiotic-treated only

-pet/-sib/0ab = control group
 -pet/+sib/0ab
 -pet/-sib/1ab = ab control group
 -pet/+sib/1ab = Does siblings matter?

+pet/-sib/0ab
 +pet/+sib/0ab
 +pet/-sib/1ab = does pets matter?
 +pet/+sib/1ab = combined effect of pets/sib

Temporal difference in microbiota (control vs ab control)

Extract taxonomic data from each group - make beta diversity analysis. At which point do we stop seeing a significant difference in the two control groups?

relative abundance -antibiotic -sib

Week 1 - difference?

noter

different distance methods can give the different results. That is because the different distance metrics consider different things. For example, bray cutis considers only the bacterial community abundance but weighted unifrac consider both the bacterial community abundance and phylogenetic distances between the different bacteria. So please do not worry about the "negative" results which are actually reasonable.

- do we have to take into consideration the abundance for each time point (it is up to the questions you want to answer. but your analysis results make sense and usually antibiotics only have a short term role on bacteria).

need to make a two paired test too.

No sibling or pets and born normally(weighted UniFrac)

Bray only with feces
